Motivation

Rheumatoid Arthritis – case-control
High School and Beyond - survey
CAN DO FV – Phase 3 RCT

The Johnson-Neyman (J-N)
Examples
Final Comment
Motivation: RA Case-Control Example

- Autoantibodies are present years prior to the onset of symptoms of rheumatoid arthritis (RA) and may be highly predictive of the development of RA

- Interest in determining *when* the autoantibodies are elevated prior to diagnosis of RA
Motivation: RA Case-Control Example

- Autoantibodies are present years prior to the onset of symptoms of rheumatoid arthritis (RA) and may be highly predictive of the development of RA

- Interest in determining *when* the autoantibodies are elevated prior to diagnosis of RA
RA Case Control Study

• SERA study
  • retrospective case-control study of RA subjects 13.67 years (4994 days) prior to diagnosis

• Study Sample
  • 166 subjects
    • 83 controls and 83 cases
      • 486 measurements
        • 1 to 4 measurements per subject

High School and Beyond Survey

- Study the relationship between mathematics achievement score (MA) and socioeconomic status score (SES) between sectors: Catholic (n=70) and public (n= 90) high schools
  - SES = a composite score of parental income, education, occupation and achievement
  - A subset of the data from the High School and Beyond Survey (HSBS) of 7,185 students nested within 160 high schools, which averaged 45 students per school
  - This study can address important questions:
    - 1) What range of SES does the mathematics achievement scores statistically differ between private and public high schools
    - 2) Which school sector does better, Catholic or Public High Schools?
High School and Beyond Survey

![Graph showing the difference in math achievement vs. relative student SES.](image)
High School and Beyond Survey

![Graph showing odds ratio against relative student SES](image)
We are interested in detecting and exploring patterns of heterogeneity of treatment effect (e.g., odds ratio).

- Identify *people* who respond differently to treatment.
- Identify *who* may benefit the most (or the least) from a treatment so treatment can be *tailored* to the individual.

We proceed by studying

- Differences *(heterogeneity)* between groups for varying values of a baseline covariate based on a model.
CAN DO Fluoride Varnish (FV)

- **Variables**
  - Primary Outcome (Dichotomous): Any Caries Incidence
  - Treatment: FV + parental counseling vs. counseling alone
  - Baseline Covariate (Continuous): Salivary Mutans Streptococci (MS) (CFU/ml))

- **Study Sample**
  - 249 caries-free children with baseline MS
  - 0 FV: n=89; 1F/Yr : n=78 ; 2FV/Yr : n=82

- **Goal**
  - At what values of MS does FV treatment result in statistically different (heterogeneity) caries incidence?
  - Who benefits (most) from treatment?
CAN DO Fluoride Varnish (FV)

Logistic Regression Model of Caries Incidence v. No Caries Incidence with Associated Standard Error Lines

- No FV: Log Odds = -1.15 + 0.52*MS
- FV: Log Odds = -1.93 + 0.33*MS

Lazar AA, PhD
Johnson-Neyman (J-N) Approach
**Aim:** What range of the independent variable is the difference in the outcome variable statistically significant among groups (“Significance Region”)?

**Johnson-Neyman (J-N) (1936) in ANCOVA when the regression lines are not parallel**
- Solves the problem of identifying regions of significance or “Significance Region”

**Tests whether the difference in means for a particular value of the covariate between two groups is statistically significance**
- comparing computed $F$ statistics to the critical value of Fisher’s $F$ distribution
- Assumes normality and homogeneity of variance
Figure 1: Population Average Curves with Corresponding Standard Error Lines (Broken Lines)
Huiitema (1980) “explicit solution”, a simple formula that involves solving a quadratic equation, available for comparing several groups but only when the number of covariates is one.

For two or more covariates, the explicit solution is thought to be intractable.

Hunka and Leighton (1997) developed a solution for any number of possible covariates by casting the equation within a general linear model framework. But this approach cannot be solved directly, symbolic processing capabilities of computational software (e.g., Mathematica_
Improvements to J-N Approach – Hunka and Leighton (1997) 3 variables of interest

“Two Paraboloids”
Miyazaki and Maier (M-M) (2005)
- developed a procedure for determining the significance regions for correlated Gaussian distributed data involves fitting hierarchical linear mixed models (HLM)
- solved for significance region using the symbolic processing capabilities (e.g., Mathematica)

Above solutions are available for comparing groups
Significance regions (solutions) for both correlated Gaussian and non-Gaussian distributed data suitable for generalized linear (mixed) models (GL(M)M), which includes HLMs. The proposed solution can:

- Compare subjects and groups
- Adjust for covariates
- Account for Multiple Testing
- Makes use of one software package to implement the model and solution, as follows...
The conditional mean of $Y$ depends on the fixed ($\beta$) and random effects ($u$) via the linear predictor $\eta = X\beta + Zu$, where

$g\{E(Y|u)\} = \eta = X\beta + Zu$

$H_0: \theta = 0$ can be tested with a t- or F-statistic.

Let $\hat{\theta} = \tilde{C}\hat{L}C'$ and $\hat{L}$ is the empirical covariance matrix of $\hat{\beta} - \beta$ and $\hat{\theta} - \theta$; $s$=the rank of $C$, the contrast matrix.

$t(\hat{\theta}) = \frac{\hat{\theta}}{\sqrt{\hat{V}_{\hat{\theta}}}}$ and $F(\hat{\theta}) = \left[ \hat{\theta}' \left( \hat{V}_{\hat{\theta}} \right)^{-1} \hat{\theta} \right]_{sx1}^1$
Let $h$ identify subsets of linear function of $\begin{pmatrix} \beta \\ u \end{pmatrix}$

- $H_0$: $h\theta = 0$ rejected ($h\theta \neq 0$)
  $$t(h\hat{\theta}) > \sqrt{sF_{1-\alpha,s,v}}$$

- Or we can use our explicit solution to identify the significance region
  $$h_x[\theta\theta' - sF_{1-\alpha,s,v}V_\theta]h_x > 0$$

- SAS macro available to determine the significance regions
Suppose $\theta_C$ represent the difference in intercepts; $\theta_A$ denote the difference in slopes, then $\theta = \begin{pmatrix} \theta_C \\ \theta_A \end{pmatrix}$

Let $V_{\theta(C)}$, $V_{\theta(A)}$, and $Cov_{\theta(A)\theta(C)}$ be the empirical prediction error variance (V) and covariance (Cov) of $\theta_C$ and $\theta_A$

\[
(1 \ X) \begin{pmatrix} \theta_C^2 & \theta_C \theta_A \\ \theta_A \theta_C & \theta_A^2 \end{pmatrix} - sF_{1-\alpha,s,v} \begin{pmatrix} V_{\theta(C)} & Cov_{\theta(A)\theta(C)} \\ Cov_{\theta(C)\theta(A)} & V_{\theta(A)} \end{pmatrix} \begin{pmatrix} 1 \\ X \end{pmatrix} > 0
\]
Let $A = \theta_A^2 - sF_{1-\alpha,s,v}V_{\theta(A)}$, $B = 2(\theta_A \theta_C - sF_{1-\alpha,s,v}Cov_{\theta(A)\theta(C)})$, $C = \theta_C^2 - sF_{1-\alpha,s,v}V_{\theta(C)}$, and the discriminant, $D = B^2 - 4AC$

Let $X_1 = \left[\frac{-B - \sqrt{D}}{2A}\right]$ and $X_2 = \left[\frac{-B + \sqrt{D}}{2A}\right]$.

- **Case I** ($A > 0$ implies $D > 0$): $X < X_1$ or $X > X_2$
- **Case II** ($A < 0$ and $D > 0$): $X_2 < X < X_1$
- **Case III** ($D < 0$ and $A < 0$): no region

- A proof of these 3 cases has been derived

- Time (years)

Cases Population Average Curve
Controls Population Average Curve
Examples- RA Case Control Example

Figure 1: Population Average Curves and an Individual RA Curve with Corresponding Standard Error Lines (Broken)
Step 1: Determine $\Delta(x)$

- Compare the Cases and Controls Population Average Curves
  $$\Delta(x) = Y_1(x) - Y_2(x) = (a_1 + \beta_1 x) - (a_2 + \beta_2 x) = (a_1 - a_2) + x(\beta_1 - \beta_2)$$

- Compare a Case’s Curve to the Controls Population Average Curve
  $$\Delta(x) = Y_1(x) - Y_{11}(x) = (\alpha_2 + \beta_2 x) - (\alpha_1 + \beta_1 x + a_{11} + b_{11} x) = (\alpha_2 - \alpha_1 - a_{11}) + (\beta_2 - \beta_1 - b_{11}) x$$

- Compare a Case’s Curve to their Population Average Curve
  $$\Delta(x) = Y_1(x) - Y_{11}(x) = (\alpha_1 + \beta_1 x) - (\alpha_1 + \beta_1 x + a_{11} + b_{11} x) = -a_{11} - b_{11} x$$
Step 2: Re-write $\Delta(x)$

- From Step 1:
  \[
  \Delta(x) = Y_1(x) - Y_2(x) = (a_1 + \beta_1 x) - (a_2 + \beta_2 x) = (a_1 - a_2) + x(\beta_1 - \beta_2)
  \]

- Step 2: Re-Write
  \[
  \Delta(x) = (1 - x) \begin{pmatrix} a_1 - a_2 \\ \beta_1 - \beta_2 \end{pmatrix} = h_x \theta
  \]

Note that $\theta = \begin{pmatrix} \beta \\ u \end{pmatrix} = (c_1, c_2) \begin{pmatrix} \beta \\ u \end{pmatrix} = c_1 \beta + c_2 u = \begin{pmatrix} 1 & 0 & -1 & 0 \\ 0 & 1 & 1 & 0 \\ c_1 & 0 & -1 & 0 \\ c_2 & 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} \alpha_1 \\ \beta_1 \\ \alpha_2 \\ \beta_2 \end{pmatrix}$ with $c_2 = 0$
Step 3: Determine the set of x’s for which the times response curves differ

- From Step 1: Determine $\Delta(x)$
  $\Delta(x) = Y_1(x) - Y_2(x) = (a_1 + \beta_1 x) - (a_2 + \beta_2 x) = (a_1 - a_2) + x(\beta_1 - \beta_2)$

- From Step 2: Re-Write $\Delta(x)$
  $h_x \hat{\theta} = \begin{pmatrix} 1 & x \end{pmatrix} \begin{pmatrix} a_1 - a_2 \cr \beta_1 - \beta_2 \end{pmatrix} = h_x \begin{pmatrix} 1 & 0 & -1 & 0 \\
0 & 1 & 0 & -1 \end{pmatrix} \begin{pmatrix} \alpha_1 \\
\beta_1 \\
\alpha_2 \\
\beta_2 \end{pmatrix}$

- Step 3: Determine the set of x’s for which this inequality holds,
  $t^2(h_x \hat{\theta}) = \left[ \frac{h_x \hat{\theta}}{\sqrt{h_x \hat{\theta} h_x}} \right]^2 > sF_{1-a,s,v}$
Steps

1. Step 1: Determine $\Delta(x)$
2. Step 2: Re-write $\Delta(x)$ in terms of the difference between the intercepts and the difference between the slopes in matrix notation
3. Step 3: Determine the set of $x$'s for which the time response curve differ
4. Step 4: Re-write Step 3 in quadratic form such that
   
   $$h_x \left[ \dot{\hat{\theta}} - sF_{1-\alpha,s,v} \hat{V}_\delta \right] h_x' > 0$$

   and determine A, B, C and D from the quadratic formula,
   
   $$AX^2 + BX + C > 0$$

5. Step 5: Determine the significance region
Population Average Curves with Standard Error Lines (Broken)

High School and Beyond Survey

1) What range of SES does mathematics achievement scores statistically differ between private and public high schools?

2) Which school sector does better, Catholic or Public High Schools?
High School and Beyond Survey

What range of SES does the mathematics achievement scores statistically differ between the Catholic high school sector and a particular public high school (for example, school 1296)?

Does the Catholic high school sector have higher math scores than a particular public high school?
• Fit generalized linear mixed models (GLMM) of mathematics achievement score, \( y_{ij} \), for the ith student in the jth cluster (school)

\[
    y_{ij} = \beta_{0j} + \beta_{1j} (SES_{ij} - \overline{SES}_j) + e_{ij} \\
    \beta_{0j} = \gamma_{00} + \gamma_{01} \overline{SES}_j + \gamma_{02} \text{sector}_j + u_{0j} \\
    \beta_{1j} = \gamma_{10} + \gamma_{11} \overline{SES}_j + \gamma_{12} \text{sector}_j + u_{1j}
\]

• \( \overline{SES}_j \) denotes the school-averaged student SES
• sector equals 1 for Catholic (C) schools or 0 for public (P) schools
• \( e_{ij} \) represents the unobservable random vector of normally distributed errors
• \( e_{ij} \) were assumed uncorrelated with the multivariate normally distributed random effects, \( u_{ij} \), of the school mean, \( (u_{0j}) \), and SES-achievement slope \( (u_{1j}) \).
\[ EC(Y_{ij}) - EP(Y_{ij}) = \gamma_{02} + \gamma_{12}(SES_{ij} - \overline{SES}_j), \text{ where } \begin{pmatrix} 1 & x \end{pmatrix} \begin{pmatrix} 1 & 0 \\ h & c \end{pmatrix} \begin{pmatrix} \gamma_{02} \\ \gamma_{12} \end{pmatrix} = (1 \ x) \begin{pmatrix} \gamma_{02} \\ \gamma_{12} \end{pmatrix} = h\theta, \]

- Results in (over) 3839 null hypotheses of no difference in mathematical achievement scores between Catholic and public schools for each of the 3839 distinct values of relative SES, \((SES_{ij} - \overline{SES}_j)\), or \(X\).
**Intercepts and Slopes Outcome Model of Math Achievement Score:**

0.649 < MS (CFU/ml) < 6.99

CAN DO FV - children with higher baseline MS values who were randomized to receive fluoride varnish had the poorest dental caries prognosis and may have benefitted most from the preventive agent.
J-N may be an important tool in the field of personalized health care

While J-N ‘explicit solution’ assumes that the covariate has linear effects, the ‘grid’ solution does not require linearity in the covariates

J-N can make more detailed and substantial descriptions about the ‘significance region’
